

# Highly Pathogenic Avian Influenza A(H5N1) Clade 2.3.4.4b Virus in Wild Birds, Chile

Naomi Ariyama,<sup>1</sup> Catalina Pardo-Roa,<sup>1</sup> Gabriela Muñoz, Carolina Aguayo, Claudia Ávila, Christian Mathieu, Leonardo I. Almonacid, Rafael A. Medina, Barbara Brito, Magdalena Johow, Victor Neira

In December 2022, highly pathogenic avian influenza A(H5N1) clade 2.3.4.4b virus emerged in Chile. We detected H5N1 virus in 93 samples and obtained 9 whole-genome sequences of strains from wild birds. Phylogenetic analysis suggests multiple viral introductions into South America. Continued surveillance is needed to assess risks to humans and domestic poultry.

Highly pathogenic avian influenza (HPAI) A(H5N1) viruses grouped within hemagglutinin (HA) gene clade 2.3.4.4b are spreading globally and causing high mortality among domestic and wild birds (1). In addition, the viruses have spilled over to several nonavian species, including humans (2). To contain HPAI outbreaks, poultry exposed to or infected with HPAI viruses have been culled, resulting in disposal of ≈131 million domestic birds globally in 2022 (3). Therefore, HPAI viruses pose a threat not only to public health because of zoonotic potential but also to food security.

In late 2021, HPAI H5N1 virus clade 2.3.4.4b, which had spread predominantly in Europe, Asia, and Africa, was detected in wild birds in North America and, shortly after, in domestic poultry (3–5). In October 2022, this virus reached South America and was officially reported in Colombia; it later was also reported in Peru, Ecuador, and Venezuela (2). We describe detection of this virus clade in wild birds in Chile.

## The Study

In early December 2022, increased wild bird deaths were detected across the north coast of Chile (Figure 1). Wild birds, mainly pelicans, were found dead or dying (Figure 2). By December 22, 2022, the official Veterinary Services of the Agricultural and Livestock Service of Chile had collected 1,368 samples for HPAI virus detection and epidemiologic investigation: 1,080 from domestic birds and 288 from wild birds (Appendix Table 1, <https://wwwnc.cdc.gov/EID/article/29/9/23-0067-App1.pdf>). We performed a total of 578 real-time qualitative reverse transcription PCR (qRT-PCR) reactions to detect active avian influenza virus (AIV) infection and 754 agar gel immunodiffusion (AGID) tests to detect previous AIV exposure (Appendix Table 2).

We initially performed qRT-PCR by using Vet-MAX-Gold AIV Detection Kit (Applied Biosystems/Thermo Fisher Scientific, <https://www.thermofisher.com>), targeting the AIV matrix gene. Then, we tested positive samples with specific H5 qRT-PCR according to US Department of Agriculture (USDA) National Veterinary Services Laboratories standard protocols (nos. 1732.02, 1767.01, and 1768.01). We tested 13 tissue samples, 2 (15%) of which were positive; 248 tracheal swab samples, 43 (17%) of which were positive; 314 cloacal swab samples, 47 (15%) of which were positive; and 3 oral swab samples, 1 (33%) of which was positive. Among all samples tested by qRT-PCR, 93 (16%) were H5 AIV-positive with cycle threshold (Ct) values <40. Among positive samples, 18 were from the Arica y Parinacota region, 18 were from Tarapaca, 53 were from Antofagasta, and 4 were from Atacama (Figure 1). No domestic poultry samples were AIV-positive, but among wild bird species, H5 AIV was detected most frequently among Peruvian pelicans (*Pelecanus thagus*) (n = 50, 54%), turkey vultures

<sup>1</sup>These first authors contributed equally to this article.

(*Cathartes aura*) (n = 12, 13%), and Peruvian boobies (*Sula variegata*) (n = 10, 11%) (Appendix Table 1).

We evaluated 754 serum samples by using the official AGID against AIV antigens ribonucleoprotein and matrix protein, according to USDA protocols ([https://www.aphis.usda.gov/animal\\_health/lab\\_info\\_services/downloads/Avian\\_AGID\\_SOP.pdf](https://www.aphis.usda.gov/animal_health/lab_info_services/downloads/Avian_AGID_SOP.pdf)) (6). We found no positive serum samples (Appendix Table 2).

We selected 11 H5 AIV-positive samples from the initial outbreak according to Ct values (Ct <27) and location; 9 samples were from pelicans and 2 from gulls, representing 3 administrative regions of Chile. We obtained whole-genome AIV sequences by initial amplification using a multisegment 1-step RT-PCR (7), then performed next-generation nanopore

sequencing by using the Native Barcoding Kit 96 and MinION platform (Oxford Nanopore Technologies, <https://nanoporetech.com>), according to the manufacturer's instructions. We filtered nanopore reads in FASTQ (<https://github.com/mcollina/fastq>) according to the average quality (Phred score  $\geq 7$ ) and length  $\leq 2,600$  bp by using NanoFit (8). We assembled genomes according to reference by using the nanopore ARTIC pipeline version 1.2.3 (<https://artic.network>), which we modified by using a relevant reference and to account for the primer sets (Appendix). We used influenza strain A/*Falco rusticolus*/EdoMex/CPA-19638-22/2022(H5N1) (GenBank accession nos. OP691321-28) as the reference. We used the National Center for Biotechnology Information Influenza Virus Sequence Annotation Tool (9) to check and annotate

**Figure 1.** Distribution of samples collected and tested for HPAIV H5N1 clade 2.3.4.4b virus in wild birds, Chile. A) Map of Chile shows regions positive and negative for HPAIV. B) Detail of area in which affected birds were sampled. Size and color of circles indicate sample size and percent positivity. HPAIV, highly pathogenic avian influenza virus.

**Figure 2.** Images of Peruvian pelicans (*Pelecanus thagus*) collected and sampled for highly pathogenic avian influenza virus H5N1 clade 2.3.4.4b, Chile. A) Dead pelican found on land near shoreline; B) ill pelican in water near shoreline.

assembled genomes and conducted H5 clade classification by using an online subspecies classification tool (10). We conducted a BLAST search (<https://blast.ncbi.nlm.nih.gov/Blast.cgi>) to choose the reference from preliminary assembled contigs constructed with filtered reads that we de novo assembled by using Canu (11). We obtained sequences with a mean coverage depth of 33,381× for 10 samples; 9 of 10 genomes were complete (Appendix Table 3).

All positive samples were classified as H5 subtype clade 2.3.4.4b. We inferred Bayesian evolutionary analysis sampling trees for HA and neuraminidase (NA), and maximum-likelihood trees for internal segments (Appendix). A/Peru/LIM-003/2022 and A/Peru/LAM-002/2022 (GISAID accession nos. EPI\_ISL\_16249730 and EPI\_ISL\_16249681) were the most closely related HA sequences found in the GISAID database (12) (Appendix Figure 1). We observed similar results from phylogenies for NA and internal genes (Appendix Figures 2–8). Sequences from Peru corresponded to isolates collected in November 2022 from domestic chickens from Lima (12°S latitude) and Lambayeque (6°S latitude). On internal gene analyses, HPAI virus sequences available from Ecuador and Mexico grouped closely to the Chile–Peru subcluster (Appendix Figures 3–8). For HA, the Chile–Peru subcluster showed a nonsynonymous mutation, T392A (L131Q), previously associated with antigenic variability in H5N1 virus strains (13). We found other synonymous and nonsynonymous mutations in NA (L269M and S339P) and internal genes (Appendix Table 4), but those mutations have not been associated with phenotypic changes.

The phylogenetic tree for the HA segment showed that the sequences from Chile and Peru were closely related to a recent ancestor from North America that was detected during October–November

2022, and the Chile–Peru sequences had closely related ancestors among strains from North America (Appendix Figure 1). A sequence from Ecuador grouped in a paraphyletic branch with different sequences from North America and had a time to most recent common ancestor estimated at August 27, 2022 (95% highest posterior density July 10–September 21). The sequences from Venezuela had a longer branch in the phylogeny reconstruction. Those sequences were more closely related to strains collected earlier in the year from North America and had a time to most recent common ancestor estimated at February 2, 2022 (95% highest posterior density January 15–February 23). The NA, matrix, and polymerase acidic sequences from Venezuela also grouped outside the Chile–Peru subcluster in the maximum-likelihood phylogenies (Appendix Figures 2, 5, 7). The phylogenetic clustering with different sequences from North America suggests that viruses from Venezuela might have resulted from separate introductions into South America. However, because of the low availability of HPAI H5N1 virus sequences from Central and South America, conclusions on the origin of the cluster in Chile are limited.

Previous studies suggest that the HPAI H5N1 virus clade 2.3.4.4b was introduced into North America multiple times across the East Asia–Australasia/Pacific and Atlantic Flyways and was subsequently disseminated to other flyways (4,14,15). The flyways reach the southernmost tip of South America, representing a high-risk route for HPAIV dissemination across the continent.

## Conclusions

According to official data, as of January 18, 2023, HPAI H5N1 viruses have disseminated as far as the

Maule region (35 south latitude) of Chile; no poultry cases have been confirmed. The Agricultural and Livestock Service of Chile implemented a contingency plan to perform extensive surveillance and reinforce biosecurity measurements to avoid introduction of HPAI virus into domestic poultry. The impact of HPAI H5N1 virus in the country, and the potential for introduction of the virus from Chile to Antarctica, remain to be fully elucidated.

### Acknowledgments

We thank the Agricultural and Livestock Service (SAG) personnel for their support and contributions, especially in sample collection. We are grateful to Belen Aguero and Felipe Berrios for their help in sample processing. We are grateful to the GISAID EpiFlu Database, laboratories, and source of original data of influenza A virus sequences, especially to the Servicio Nacional de Sanidad Agraria del Perú-SENASA, Peru, source of the closest strains.

This study was funded by Fondecyt 1211517 (to V.N.) and the Center for Research on Influenza Pathogenesis and Transmission (contract no. 75N93021C00014, awarded to R.A.M. and V.N.) and Emory CEIRR (contract no. 75N93021C00017 awarded to C.P.R., V.N., and R.A.M.), both part of the National Institute of Allergy and Infectious Diseases Centers of Excellence for Influenza Research and Surveillance.

### About the Author

Dr. Ariyama is a veterinarian and PhD candidate at the University of Chile, Santiago, Chile. Her primary focus is the study of emerging viral zoonotic pathogens.

Dr. Pardo-Roa is an assistant professor at the Molecular Virology Laboratory at Pontificia Universidad Católica de Chile, Santiago, Chile. Her focus is the study of influenza A viruses and next generation sequencing technologies.

# Highly Pathogenic Avian Influenza H5N1 Clade 2.3.4.4b Virus in Wild Birds, Chile

## Appendix

### Genome Assembly

Nanopore ARTIC pipeline was changed as follows: first, the reference sequence was changed to the influenza isolate *A/Falco\_rusticolus/EdoMex/CPA-19638–22/2022(H5N1)*, GenBank accession nos. OP691321 to OP691328. Then, primer bed files were changed to match the PCR primers used to amplify the genome. For the pool field (fifth column) all entries were set to 1. Next, all alignments in the BAM file were used, so option “–normalise” of align\_trim software was set to the maximum number of reads. Finally, only medaka consensus with option–RG 1 was used (given that there is only one pool of primers for flu and not two like for SARS-CoV-2); RG 2 was not used.

### Phylogenetic Analyses

Datasets for each influenza viral segment sequence were created by retrieving reference sequences from NCBI (1) and GISAID databases (2). The sequences were aligned using MUSCLE (3) in Mega X (4). Duplicate sequences were removed, and the phylogeny was estimated using the maximum likelihood method available in IQ-TREE version 2.1.2 (<http://www.iqtree.org>), employing -m TEST option for nucleotide substitution model selections and 1,000 ultrafast bootstrap replications in CIPRES (5,6). Each phylogenetic tree was visualized using Figtree (<http://tree.bio.ed.ac.uk/software/figtree>). Also, we performed Bayesian evolutionary analysis by sampling trees (BEAST) analysis for the HA and NA segment (7).

\*Ct, cycle threshold; NA, not applicable; ND, not determined; RT-PCR, reverse transcription PCR.

†Pooled samples correspond to paired cloacal and tracheal swabs for wild bird surveillance; for commercial birds, first detection could be performed using pooled samples of up to 5 tracheal or cloacal swabs per location.

**Appendix Table 2.** Number of serum samples of domestic and wild birds tested with agar gel immunodiffusion tests (AGID) against Influenza A virus antigens, December 2022, Chile\*

Species	No. serum samples
Domestic birds, total	749
Laying hen ( <i>Gallus gallus domesticus</i> )	542
Backyard hen ( <i>G. gallus domesticus</i> )	200
Backyard goose ( <i>Anser anser domesticus</i> )	4
Domestic duck ( <i>Anas platyrhynchos domesticus</i> )	3
Wild birds, total	5
Gull ( <i>Larus</i> sp.)	3
American kestrel ( <i>Falco sparverius</i> )	1
Species not determined	1
Total	754

\*Samples tested with agar gel immunodiffusion tests against Influenza A virus antigens (ribonucleoprotein and matrix protein). No positive samples were found from December 1–22, 2022.

**Appendix Table 3.** Summary of sequencing results of highly pathogenic avian influenza virus H5N1 clade 2.3.4.4b in wild birds, December 2022, Chile\*

\*Species correspond to Peruvian pelican (*Pelecanus thagus*) and Belcher's gull (*Larus belcheri*). HA, hemagglutinin; MP, matrix protein; NA, neuraminidase; NP, nucleoprotein; NS, nonstructural; PA, polymerase acidic; PB1, polymerase basic protein 1; PB2, polymerase basic protein 2.

**Appendix Table 4.** Featured mutations found in highly pathogenic avian influenza H5N1 viral strains from Chile sequenced in this study compared with all stains included in the dataset of each viral segment phylogenetic analyses\*

Segment	Nucleotide	Synonymous	Amino acid	Comments
HA	T392A	No	L131Q	Unique for the cluster containing Chilean strains
	C549T	Yes		Unique for the cluster containing Chilean strains
	G1686A	Yes		Unique for the cluster containing Chilean strains
NA	T805A	No	L269M	Unique for the cluster containing Chilean strains
	T1015C	No	S339P	Unique for the cluster containing Chilean strains
	C444A	Yes		Unique for the cluster containing Chilean strains
	G696T	Yes		Unique for the cluster containing Chilean strains
M	A254G	No	N85S	Unique for the cluster containing Chilean strains
	A260C	No	N87T	Unique for Peruvian and Chilean strains
	G333T	Yes		Unique for Peruvian and Chilean strains
PB2	A1846G	No	I616V	Unique for the cluster containing Chilean strains
	C2035T	No	P679S	Unique for A/Pelican/Chile/226955–1/2022(H5N1)
	A1155T	Yes		Unique for Chilean strains
	A1846G	Yes		Unique for the cluster containing Chilean strains
PB1	C1132A	No	L378M	Unique for Peruvian and Chilean strains
	G1196A	No	G399D	Unique for Peruvian and Chilean strains
	T1542C	No	S515A	Unique for Chilean strains except A/Pelican/Chile/226924–1/2022(H5N1) and A/Seagull/Chile/227023–3/2022(H5N1)
				Unique for South American strains
PA	G170A	No	R53Q	Unique for Peruvian and Chilean strains
NS1	T346A	No	C116S	Unique for Peruvian and Chilean strains
	C668A	No	A223E	Unique for the cluster containing Chilean strains
	G721T	No	A241S	Unique for Peruvian and Chilean strains
NP	T688C	No	F230L	Unique for Peruvian and Chilean strains
	C1317T	Yes		Unique for Peruvian and Chilean strains

\*NCBI (<https://www.ncbi.nlm.nih.gov>) and GISAID (<https://www.gisaid.org>) databases. HA, hemagglutinin; M, matrix; NA, neuraminidase; NP, nucleoprotein; NS1, nonstructural protein 1; PA, polymerase acidic; PB1, polymerase basic protein 1; PB2, polymerase basic protein 2

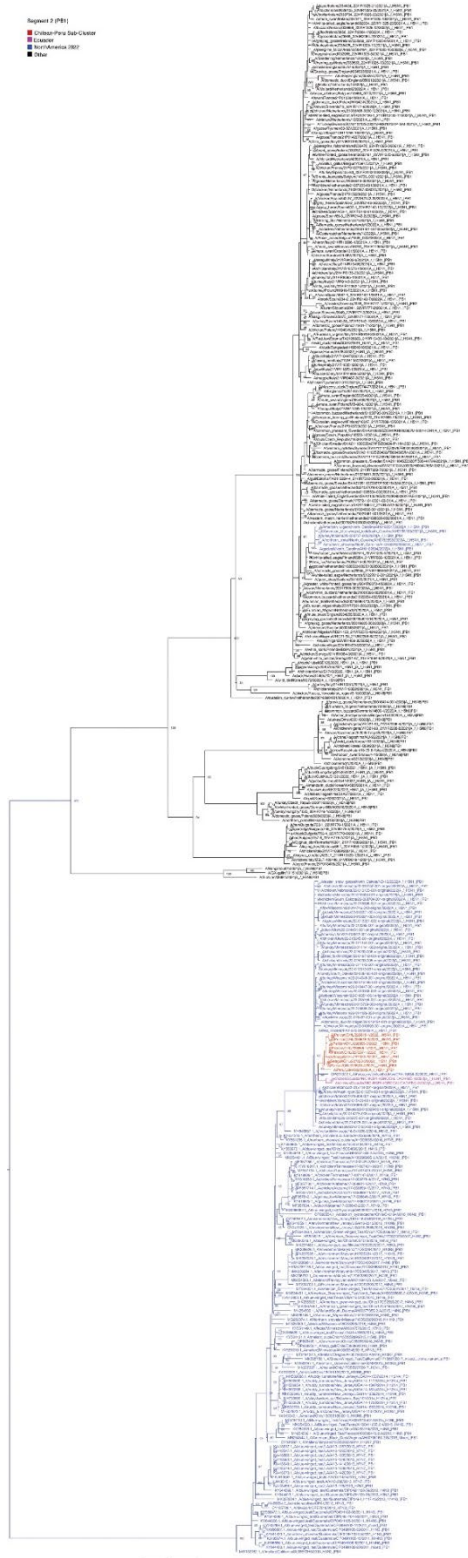

**Appendix Figure 1.** Bayesian evolutionary analysis sampling tree of hemagglutinin protein of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.

**Appendix Figure 2.** Bayesian evolutionary analysis sampling tree of neuraminidase protein of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.

**Appendix Figure 3.** Maximum likelihood phylogenetic tree depicting the phylogeny of polymerase basic protein 1 (PB1) from isolates of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b H5 clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.

**Appendix Figure 4.** Maximum likelihood phylogenetic tree depicting the phylogeny of polymerase basic protein 2 (PB2) from isolates of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b H5 clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.

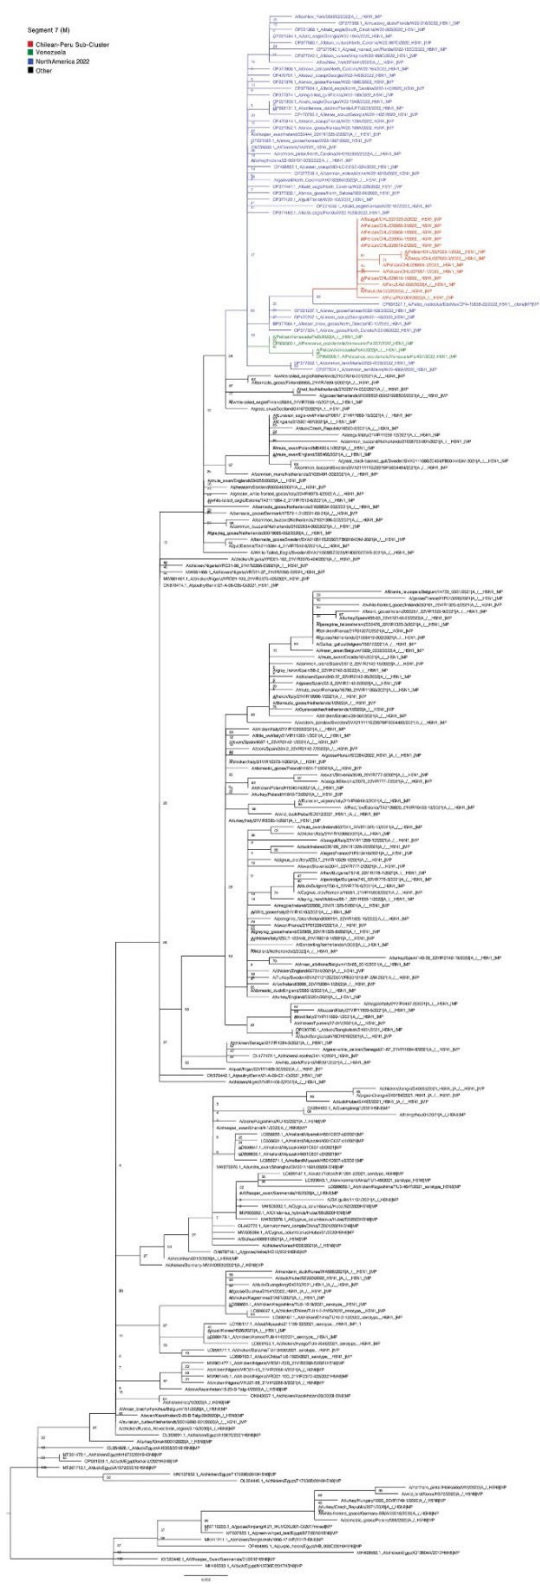

**Appendix Figure 5.** Maximum likelihood phylogenetic tree depicting the phylogeny of polymerase acidic (PA) segment from isolates of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b H5 clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.

**Appendix Figure 6.** Maximum likelihood phylogenetic tree depicting the phylogeny of nucleoprotein (NP) segment from isolates of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b H5 clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.

**Appendix Figure 7.** Maximum likelihood phylogenetic tree depicting the phylogeny of matrix (M) segment from isolates of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b H5 clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.

**Appendix Figure 8.** Maximum likelihood phylogenetic tree depicting the phylogeny of nonstructural protein (NP) from isolates of highly pathogenic avian influenza H5N1 subtype 2.3.4.4b H5 clade virus, Chile, 2022. Scale bar indicates nucleotide substitutions per site.
