# **Purpose**

NIOSH found that it is not possible to completely reconstruct uranium and thorium internal radiation doses at Joslyn Manufacturing and Supply Co. (Joslyn), in Fort Wayne, Indiana, for the time period of March 1, 1943 through July 31, 1947. NIOSH finds that dose reconstruction is possible for the remaining covered time period of August 1, 1948 through December 31, 1952. This White Paper discusses the NIOSH-proposed dose reconstruction (DR) methods at the Joslyn facility for the workers not included in the Special Exposure Cohort, as well as for the partial DR methods for the SEC time period. The methods described in this document are intended to supplement (and in some cases replace) the methods provided in the Joslyn SEC ER and ER Addendum<sup>1</sup>.

# **Internal Dose**

There was no bioassay monitoring at Joslyn and a limited number of air samples taken during the entire covered period. In the ER, NIOSH compared the Joslyn-specific air sampling data to the air sampling data for the corresponding time periods in Battelle-TBD-6000, *Site Profiles for Atomic Weapons Employers that Worked Uranium Metals*. Because the Joslyn dataset has limitations on its use for dose reconstruction, NIOSH chose to initiate this comparison to verify if the well-validated data set of Battelle-TBD-6000 was an appropriate upper bound for the available Joslyn data. NOSH compared the 1952 Joslyn un-weighted breathing zone (BZ) air concentration data for rolling operations to the Battelle-TBD-6000 Finishing Roll Operator and Rouging Roll Operator air concentration data, which are the two highest-exposure rolling jobs documented in Battelle TBD-6000. While the purpose and end uses of the uranium products coming out of Joslyn after 1948 changed, the basic product (rolled and finished rods) did not. While it is reasonable to presume that the Rolling Operator values would continue to represent the highest-exposure jobs at Joslyn following the production rolling period in 1948, NIOSH has included both the Rolling and Machining Operator categories. Table A-1 of Attachment A provides a listing of uranium rolling days. Table A-2 of Attachment A lists uranium machining days. Table A-3 of the same attachment provides a list of thorium rolling and machining days for the covered time period at Joslyn.

Tables A-4 and A-5 of Attachment A provide a comparison between the Joslyn rolling operation air concentration data and the Battelle-TBD-6000 air concentration data that was depicted in the ER. The 1952 study presented in Table A-4 is the only time-weighted-average (TWA) study located for Joslyn. As can be seen, each arithmetic mean (AM) of the distribution with the given geometric mean (GM) and a geometric standard deviation (GSD) of 5 is generally much higher than the 1952 TWA values obtained at Joslyn. In one location ("9-inch finishing roll east"), the Joslyn value was higher. A similar comparison was also made for the limited centerless grinding data in 1951. In this case, TWA values were not available, but the average and maximum values of the Joslyn data were compared to Battelle-TBD-6000. The results are provided in Table A-5. The conclusion is that results favorable to claimants at Joslyn would be obtained by using the machining and rolling operator categories from Battelle-TBD-6000. Only the operator category shall be used for dose reconstruction in order to insure that the data is bounding for internal dose beginning in August of 1948. These are reproductions of tables 7-8 [inhalation] and Table 7-9 [ingestion], which appeared in ER Rev. 1. The conclusion was that results favorable to claimants at Joslyn would be obtained in Rev. 1 of the Joslyn ER as Table 7-3; this table is reproduced as Table A-6.

Page 2 of 20

<sup>&</sup>lt;sup>1</sup> It should be noted that Tables 7-1 and 7-2 and Figures 7-1 and 7-2 from Rev. 1 of the Joslyn ER have been updated and corrected in this white paper as revised in the ER Addendum to address an uncertainty calculation correction and a TWA timeframe adjustment from 2,400 to 2,200 work hours per year for the purpose of converting Battelle-TBD-6000 intake rates to an estimated airborne concentration for comparison to the 1952 Joslyn air data.

This working document prepared by NIOSH or its contractor for use in discussions with the ABRWH or its Working Groups or Subcommittees. Draft, preliminary, interim, and White Paper documents are not final NIOSH or ABRWH (or their technical support and review contractors) positions unless specifically marked as such. ### Description of DR methods for internal dose:

- The uranium exposure rates in Table B-6 associated with rolling and machining operations are based on a single shift per workday. For situations where an employee may have worked multiple shifts, these intakes are to be adjusted to account for the longer exposures times. In addition, for situations where rolling and machining operations may have occurred on the same day, the larger of the two exposure rates (but not both) will be applied.
- For the worker's employment period, determine the number of days that uranium was rolled and machined in each year based on research summarized in Tables A-1 and A-2.
- For each operational day, assign intakes based on the intake rates in Battelle-TBD-6000, Table 7.8 (inhalation) and Table 7.9 (ingestion) also in ER Rev. 1 as Table 7-3 and here as Table A-6). Please note that since the intake rates in Battelle-TBD-6000 are based on 365 calendar days/year, it will be necessary to convert the intake rates to 250 workdays per year (i.e., to multiply the intake rates by 365/250). These daily intakes will then be multiplied by the number of rolling or machining days to arrive at a total annual intake per year.
- The operator category shall be assumed for all workers.
- For each non-operational day (i.e., no rolling or machining), assign inhalation intakes based on the method described Battelle-TBD-6000, Section 7.1.5, using the operator category for all workers. Intakes should be based on the following assumptions: operational air concentration of 2,491 pCi/m3; deposition velocity of 7.5E-04 m/s; deposition time of 30 days; and a re-suspension factor of 1E-5 m<sup>-1</sup>. This results in an intake rate for inhalation of 558 pCi per non-operational workday.
- For each non-operational day (i.e., no rolling or machining), ingestion intakes are assigned to be equal to the ingestion intakes for machining during the operational period. This results in an ingestion intake rate of 588 pCi per non-operational workday prior to 1951, and 539 pCi per non-operational workday for 1951 forward.
- For each year of employment, sum the inhalation and ingestion intakes for both operational and non-operational days, as determined above, and assign assuming 100% uranium-234.
- For determining the probability of causation (POC), the doses determined above are treated as the geometric mean (GM) of a lognormal distribution with geometric standard deviation (GSD) of 5.

### <u>Thorium</u>

Extruded thorium rods were centerless ground and medart straightened on two occasions at Joslyn Manufacturing. Although the centerless grinding operations could have created respirable particles, the work was performed under wet conditions for cooling purposes. Furthermore, these operations occurred during the SEC period for which NIOSH has determined it is not feasible to reconstruct internal exposures adequately. Consequently, no internal dose is assigned from thorium operations.

# On-site Environmental

Environmental internal doses will not be assigned; only the occupational doses determined by using the above procedure, which accounts for any environmental internal exposures, will be employed for all claimants.

# External Dose

The principal sources of external radiation doses for members of the evaluated class were exposure to gamma and beta radiation associated with handling and working in proximity to uranium and uranium compounds while involved in the hot rolling, quenching, straightening, grinding, and cutting of the materials. Some employees were also potentially externally exposed to the radiation from re-suspended contamination from uranium metal surfaces and the floor during the course of their work with these radioactive materials. The metal workers were assumed to have been provided annual medical chest X-rays examinations as part of the hazard and health monitoring of these workers.

Since no dosimetry information is available for Joslyn employees, NIOSH will bound the external exposures and reconstruct the doses to an employee by using the models, guidance, and default bounding values in Battelle-TBD-6000, ORAUT-OTIB-0006, and ORAUT-OTIB-0079. NIOSH will employ these resources to calculate external beta and gamma doses from working, as an Operator in the Joslyn plant for all covered years. In addition, occupational medical doses from annual X-ray examinations will be assigned for this period of employment.

NIOSH understands that exposure to the uranium metal was not a continuous exposure over the course of the year; thus, annualized exposure calculations would be a significant overestimate of the actual exposure potential. Specific rolling dates are provided in the example DR below.

DR methods for external dose:

- For each operational day, external doses are based on the exposure rate for the "long billet" at 30.48 cm provided in Battelle-TBD-6000, Table 6.1. For purposes of dose reconstruction, the numbers of rolling days-per-year in the Example DR, Attachment A, Table A-1 are assumed to apply to both rolling and machining operations. (See Table A-7 for dose values.)
- Use 10 times the gamma exposure rates at one foot for the beta (skin) exposure rate per guidance in Battelle-TBD-6000, Section 3.3.1. (See Table A-7 for dose values.)
- For each non-operational day, external doses are based on the exposure rate associated with contaminated air and surfaces provided in Battelle-TBD-6000, Tables 3.9 and 3.10. The non-operational days in Table B-1 represent the number of days that the workers were in the plant but not performing uranium rolling or machining operations. (See Table A-7 for dose values.)
- Occupational X-ray doses are extracted from ORAUT-OTIB-0006 Appendix A in Table A-7 for the Lung and Entrance Skin for the PA X-ray projection; each is multiplied by the number of years employed for a total dose for the two organs for the number of years worked.
- The dose from submersion in the contaminated plant air for the employment period is determined from Battelle-TBD-6000, Table 3.9, and is found to be trivial.

Page 4 of 20

This working document prepared by NIOSH or its contractor for use in discussions with the ABRWH or its Working Groups or Subcommittees. Draft, preliminary, interim, and White Paper documents are not final NIOSH or ABRWH (or their technical support and review contractors) positions unless specifically marked as such. This document represents preliminary positions taken on technical issues prepared by NIOSH or its contractor. **NOTICE: This information is protected by the** <u>Privacy Act 5 USC §552a</u>; disclosure to any third party without the written consent of the individual(s) to whom the information pertains is strictly prohibited

- For each year of employment, sum the annual dose for both rolling and non-operational days, as determined above, making sure that any annual dose rates from Battelle-TBD-6000 have been normalized to 250 days of exposure.
- For determining the probability of causation (POC), the doses determined above are treated as the geometric mean (GM) of a lognormal distribution with geometric standard deviation (GSD) of 5.

### <u>Thorium</u>

The Battelle-TBD-6000 modeling for uranium metal was adjusted to thorium dose rates using a computer model MCNPX. The estimated dose rate is provided in Table B-8. These doses are applied in IREP as a lognormal distribution with a GSD of 5.

Thorium has a significant number of higher-energy photons in the Th-232 decay chain. Based on the half-lives of the progeny, only a partial equilibrium is possible; therefore, it is conservative to state that equilibrium would be reached in this decay chain. It has been assumed that Ra-228 and Th-228 progeny were in equilibrium with Th-232. Under this assumption, the progeny are the major source of both penetrating and non-penetrating external exposure.

### Photon Dose

Photon dose at Joslyn would be primarily made up of Operator exposure to photons from the uranium metal being worked at the site, with exposure to contaminated surfaces being a lesser dose contributor. While the preferred indicators of external dose are dosimetry measurements, NIOSH has not identified any personnel external monitoring records or personal dosimetry data associated with the uranium processing conducted during the period under evaluation. Battelle-TBD-6000, Section 6.2, provides guidance on estimating external dose rates due to penetrating radiation emitted from the surface of uranium metal. Using the results of Monte Carlo N-Particle Transport Code (MCNP) calculations performed for a number of basic shapes, it provides calculated dose rates for distances of one centimeter, one foot, and one meter from the surface of the natural uranium metal. These dose rates are used to estimate the component of whole-body dose that a worker would receive while handling or near uranium metal, applying information that may be available about the specific conditions of a worker's likely exposure. If no information is available about the specific conditions of exposure, Battelle-TBD-6000 provides for generic worst-case assumptions to be made about a worker's exposure conditions.

Dose reconstruction at Jolsyn will use the operator category for all employees. The potential exposure accrued from the presence of contamination on work surfaces would be minor in comparison with the primary exposure to the uranium metal.

# Beta Dose

Non-penetrating beta dose is primarily associated with the hands and forearms, and then other skin surfaces, of a worker who handles uranium metal in close proximity. Battelle-TBD-6000, Section 6.3, details a method to estimate skin doses for the hands and forearms of a worker who handles uranium metal as well as the other skin surfaces.

### Medical X-ray Dose

Although NIOSH has not located specific parameters associated with occupational medical X-rays (i.e., specific information on the X-ray devices), default values of entrance kerma, developed for the most commonly-used

occupational medical diagnostic procedures, are available in ORAUT-OTIB-0006. These values can be used to support bounding the medical X-ray dose for the time period under evaluation. These default values are maximum or upper limit values developed from: review of patient doses reported in the literature; machine characteristics; and knowledge of X-ray procedures used during different historical time periods. These default values can be used in lieu of actual measurement data, or entrance kerma derived from technique factors, to bound the occupational X-ray exposures for Joslyn uranium and thorium workers from March 1, 1943 through December 31, 1952. For dose reconstruction purposes, a pre-employment, post-employment, and annual examination is assumed during the operational period, per guidance in ORAUT-OTIB-0079.

#### Example DR:

Attachment B on the beginning provides an example dose reconstruction using the approach described in this white paper.

Grinder (portable)	125	Machining Operator	2491	35171	9096
Cutomatic	86	Machining Operator	2491	35171	9096

The 1952 study presented in Table 4 above is the only time-weighted-average (TWA) study located for Joslyn. As can be seen, each arithmetic mean (AM) of the distribution with the given geometric mean (GM) and a geometric standard deviation (GSD) of 5 is generally much higher than the 1952 TWA values obtained at Joslyn. In one location ("9-inch finishing roll east"), the Joslyn value is higher.

# Attachment B

# Joslyn Example Dose Reconstruction for the Post-SEC Period (August 1948 on)

#### Employee Information

Cancer Description:	Lung (ICD-9: 162); diagnosed 12/31/1977	
	Prostate diagnosed (ICD9 185); diagnosed 12/31/1977	
	BCC of the back (ICD-9: 173); diagnosed 12/31/1977	
	SCC of the back (ICD-9: 173); diagnosed 12/31/1977	
	Kidney; diagnosed 12/31/1977	
	Liver; diagnosed 12/31/1977	
Year of birth:	1923	
Gender:	Male	
Smoking:	Former Smoker	
Ethnicity:	"White, non-Hispanic"	

### **Employment Information**

Employer:	Joslyn
Start date:	03/01/1943
End date:	12/31/1952
Occupation:	Operator
Dosimetry Data:	None

Page 14 of 20

# Organ Dose Assessed<sup>3</sup>

The organs evaluated in the Example DR are shown in Table B-1.

Table B-1: Example DR Evaluated Organs				
Cancer	External Organ Used	Internal Organ Used		
Lung	]Lung	Lung		
Prostate	Urinary Bladder	Non-Metabolic Organ with Highest Dose (Adrenals/Brain)		
Skin	Skin	Skin		
Kidney	Liver	Kidney		
Liver	Liver	Liver		

# Internal Dose

Internal dose during the residual period was assigned in accordance with methodology presented in the SEC-00200 Joslyn SEC Evaluation Report.<sup>4</sup> Intake values tabulated in Battelle-TBD-6000 were used as a basis for the assigned inhalation and ingestion intakes<sup>6</sup>. Inhalation and ingestion intake rates from Battelle-TBD-6000, Tables 7.8 and 7.9, were used to assign intakes during rolling days. Inhalation and ingestion intake rates used to assign intakes during rolling days. Inhalation and ingestion intake rates used to assign intakes during non-operational days were based on guidance in Battelle-TBD-6000, Sections 7.1.5 and 7.1.6. The number of operational and non-operational days was based on research summarized in the Joslyn ER, as indicated in the external dose section above. The resultant intake rates are presented in Table B-2 on the next page.

April	2014
-	

Year	Rolling Days	Machining Days	Rolling and Machining Days	Non-Operational Days	Inhalation Intake Rate (pCi/year)	Ingestion Intake Rate (pCi/year)
1943 <sup>a,c</sup>	1	16	1	190	0	0
1944 <sup>c</sup>	23	10	6	207	0	0
1945°	0	0	54	196	0	0
1946 <sup>c</sup>	0	1	32	217	0	0
1947°	0	0	12	238	0	0
1/7/1948°	0	8	67	71	0	0
8- 12/1948	10 <sup>b</sup>	0	0	94	237,435	59,104
1949	2	0	0	248	175,348	146,677
1950	8	3	0	239	367,409	145,425
1951	1	1	0	248	170,081	134,494
1952	3	1	0	246	202,974	134,111

a. 1943 is a partial year (March through December); therefore, the 250 workdays were prorated by 10/12 to account for this.

b. SRDB 112574 indicates a rolling operation occurred sometime between 1947 and 1050 for 10 days. Therefore it was assumed to have all occurred in 1948 to be claimant favorable, since 1947 is covered under the SEC.

c. During the SEC, internal dose assessment is considered infeasible. Therefore, no intakes are assessed during this period.

### <u>Thorium</u>

Thorium operations occurred during the SEC period for which NIOSH has determined it is not feasible to reconstruct internal exposures adequately. Consequently, no internal dose is assigned from thorium operations.

### External Dose

External Dose (deep and shallow) was assigned in accordance with the SEC-00200 Joslyn SEC Evaluation Report.<sup>4</sup> A photon dose of 7.03 mrem per uranium rolling/machining day and 1.08 mrem per non-operational day was assigned. An electron dose of 70.3 mrem per uranium rolling/machining day was assigned. External exposure during uranium rolling/machining days was based on the dose rate calculated at a distance of one foot from a Long Billet<sup>6</sup>, assuming a 10-hr working day. External exposure during non-operational days was based on the dose rate calculated at a distance of one meter from a Long Billet<sup>6</sup>, assuming a 10-hr working day. The number of operational and non-operational days was determined based on site research data<sup>4</sup> and is summarized in Table B-3 on the next page.

Page 16 of 20

April	201	4

Table B-3: Estimated Annual Uranium External Exposures for Joslyn				
Year	Operational Days	Non-Operational Days	Annual Deep (mrem)	Annual Shallov (mrem)
1943 <sup>a</sup>	18	190	134	2014
1944	43	207	311	3839
1945	54	196	388	4569
1946	33	217	241	3175
1947	12	238	94	1782
1948	85 <sup>b</sup>	165	604	6626
1949	2	248	24	1118
1950	11	239	87	1716
1951	2	248	23	1037
1952	4	246	37	1170

1943 is a partial year (March through December); therefore, the 250 workdays were prorated by 10/12 to account for this. a.

SRDB 112574 indicates a rolling operation occurred sometime between 1947 and 1050 for 10 days. b.

Therefore it was assumed to have all occurred in 1948 to be claimant favorable, since 1947 is covered under the SEC.

A photon dose of 20.9 mrem per thorium rolling/machining day was assigned. A shallow dose of 6.3 mrem per thorium rolling/machining day was assigned. External exposure during thorium rolling/machining days was based on the BattelleTBD-6000 modeling for uranium metal and adjusted to thorium dose rates using a computer model MCNPX. The number of rolling and non-operational days was determined based on site research data and is summarized in Table B-4 below.

Table B-4: Estimated Annual Thorium External Exposures for Joslyn				
Year	Operational Days	Annual Shallow (mrem)		
1946	2.5	52	16	
1947	2.5	52	16	

Page 17 of 20

# Penetrating Dose

For the purpose of estimating probability of causation, all photon doses are assumed to be acute.<sup>2</sup> Photon doses were determined by applying a 100% 30–250 keV energy distribution to the reported photon doses<sup>2</sup>. The dose rate was multiplied by the deep dose mode organ dose conversion factor. An organ dose conversion factor value of 1 was used for the skin in conjunction with guidance in ORAUT-OTIB-0017. The organ dose conversion factors are shown in Table B-5 on this page.

### Non-Penetrating Dose

For the determination of non-penetrating dose, an energy distribution of 100% > 15 keV electrons has been assumed for all non-penetrating doses. The electron radiation was only considered in the dose reconstruction of the skin because it would not have added dose to the other cancer sites.

For skin cancer claims, ethnicity is necessary to determine the probability of causation.<sup>1,5</sup> The hypothetical covered employee was assumed to be "white, non-Hispanic" for the purposes of this example dose reconstruction.

Table B-5: Organ Dose Conversion Factors				
Organ	30-250 keV (mode)	Electron>15 keV		
Lung	0.695	n/a		
Prostate	0.873	n/a		
Skin	1.000	1.000		
Kidney	0.748	n/a		
Liver	0.748	n/a		

The total doses for photon and beta dose (skin only) are given in Table B-6 below.

Table B-6: Total Assigned External Dose				
Organ	Photons (rem)	Electrons (rem)		
Lung	1.422	n/a		
Prostate	1.788	n/a		
Skin	2.080	27.047		
Kidney	1.531	n/a		
Liver	1.531	n/a

1952	0.084	0.025	0.270	0.090	0.090
TOTAL	0.838	0.250	2.700	0.902	0.902

Table B-7 presents the estimated annual medical dose for Joslyn.

# Uncertainty

External photon dose for uranium was applied as a lognormal distribution with a GSD of 5. Internal dose was applied as a lognormal distribution with a GSD of 5. Occupational medical X-ray doses were assigned as a normal distribution with an uncertainty of 30%.

### Summary

The assessment methods presented in this report define the methods by which a dose estimate can be determined for employees of Joslyn during the covered period. These methods support NIOSH's conclusion that the operationally-related internal dose for the evaluated worker class can be bounded. A summary of the doses and probability of causations are provided in Table B-8 on the next page.

Table B-8: Summary of the Doses and Probability of Causations					
Cancer	External (rem)	Internal (rem)	Medical (rem)	Total (rem)	Probability of Causation
Lung	1.422	170.658	0.838	172.918	97.67%
Prostate	1.788	1.057	0.250	3.094	29.21%
Skin BCC	29.127	1.057	2.700	32.884	94.04%
Skin SCC					29.75%
Kidney	1.531	17.787	0.902	20.219	74.27%
Liver	1.531	5.952	0.902	8.384	80.22%
